
(a) Continuous Bubble-Trinity Regimes & Snapping Failure
Kernel-induced line Hamiltonian $\mathcal{H}_{\text{ind}}(t)$
Continuous Langevin integration step t ($\Delta t = 0.025$)
Kernel energy drops 37.5%, yet greedy snapping fails (0%) via hard-core eviction cascades
Regime I: Frozen Crystal ($k_w = 7.0, k_f = 0$)
Regime II: Elastic Phonon Drift ($k_w = 2.6, k_f = 1.0$)
Regime III: Convective Melt ($k_w = 0.8, k_f = 3.2$)
Regime IV: Centrifugal Balance ($k_s = 0.85$)
(b) Physical Mechanism Ablation: Failed vs. Successful Analogs
Order $n = 4$ (S_{16}, 200 trials)
Order $n = 5$ (S_{25}, 100 trials)
0. Colloidal Drift + Snap (Hard-core eviction cascade)
1. Kawasaki 2-Spin Quench (Trapped by $c_{ab}d^2$ barrier)
2. Zener 3-Ring Vacancy SA (Monopole defect + thermal drift)
3. Spin-Ice (2, 2) Loop Quench (100% S_9; 1-pass quench)
4. $T1$ Foam / Eshelby STZ (Top-40 quadrupoles, 1 restart)
5. + Crystallographic Slip Glide (Row/col plane glide, 1 restart)
6. Wales-Doye / Chaperonin Re-Anchored Basin-Hopping
